To read this article in Chinese, please see the article's Supporting Information on Wiley Online Library ([wileyonlinelibrary.com/journal/famp](http://wileyonlinelibrary.com/journal/famp)).

The grounded theory method was used to analyze the parenting styles used by caregivers to rear children with autism spectrum disorders (ASD) and to investigate parents' experiences regarding how to help their child overcome the symptoms. Thirty-two parents from 28 families of children with ASD in mainland China were interviewed. Analysis of interview transcripts revealed four patterns of parenting styles which varied in affiliation to the roles of caretaker and coach. Based on their experience, a sizable group of parents perceived that their own emotions influence the child's emotions and his/her symptoms. The results suggest the value of developing intervention programs on emotion regulation and positive parenting for the parents of children with ASD.

**Keywords:** Autism Spectrum Disorder; Parenting Style; Emotion Transmission; Emotion-Symptom Link

*Fam Proc* 53:67–79, 2014

Autism spectrum disorder (ASD) is a pervasive developmental disorder which includes social impairment, communication difficulties, and high levels of repetitive behavior (American Psychiatric Association, 2000). Because of its high incidence, unclear etiology, and the need for effective intervention and prognosis, it has received much attention in recent years.

Rearing a child with ASD is a great challenge for parents. A case et al. (2012) argued, the diagnosis of ASD is a major concern for affected families. Such parents might feel from potential social isolation and social isolation, lack of professional support, and high incidence. A number of studies have demonstrated that parents face unique difficulties and challenges, such as emotional problems, physical health problems, and social isolation. In general, the diagnosis of children with autism谱系障碍 is associated with social isolation and social isolation, and the degree of social isolation is higher than that of other mental disorders (Ingraham & Hambrick, 2011; Rao & Beidel, 2009; Wei, 2002). Belief regarding parenting style also impacts the diagnosis of autism谱系障碍. Such parents are more likely to believe that they are not competent in helping their children cope with social situations. Compared with other mental disorders, the social isolation of parents of children with autism谱系障碍 is more pronounced (Hall, Roe, & McDonald, 2005; Khan & Carter, 2006; Meier et al., 2010).

Children's physical development and social development are closely related to their physical health and social health. The former has been shown to have a significant influence on the latter. For example, in addition to social isolation, there is a bidirectional relationship between social isolation and mental health. The former has been shown to have a significant influence on the latter.

child<sup>d</sup> en. For example, Binké, Seifé, and Samé off (1994) found that parents often can predict the development of children with autism spectrum disorder (ASD) based on their behavior. In addition, it is also found that parents of children with ASD have included the child in their social activities, such as sports and other social activities, and the child's participation in learning activities is often higher than that of typically developing children (Robbin, D'Innapoli, & Plieni, 1991). In addition, parents of children with ASD have been found to have specific interests in their children's education (O'bryan, McHugh, Sanderson, & Reed, 2008a). However, the self-efficacy among parents is also associated with the engagement of children with autism spectrum disorder (O'bryan & Reed, 2010).

Although the effectiveness of parenting interventions for children with ASD has been limited, effective parenting interventions for children with ASD have been developed. For example, the "parenting of children with autism spectrum disorder" intervention developed by Lambrecht, Van Leeuwen, Boonen, Mae, & Noen (2011) has been found to be effective. This intervention includes coaching, modeling, and reinforcement. The coaching part involves training parents to help their children with autism spectrum disorder communicate effectively. The modeling part involves observing and imitating the behavior of other parents who have successfully helped their children with autism spectrum disorder. The reinforcement part involves rewarding parents for their efforts. The results show that this intervention is effective in improving the quality of life of parents of children with autism spectrum disorder (Hoogenboom & Woodgate, 2012; Tai et al., 2008). Although the effectiveness of parenting interventions for children with autism spectrum disorder has been demonstrated, there is still a need for further research to identify more effective interventions.

To summarize, although the effectiveness of parenting interventions for children with autism spectrum disorder has been demonstrated, there is still a need for further research to identify more effective interventions. The effectiveness of parenting interventions for children with autism spectrum disorder may depend on various factors, such as the severity of the child's autism, the family's cultural background, and the availability of resources. Therefore, it is important to develop interventions that are tailored to the specific needs of each family.

This study focused on the parenting of children with autism spectrum disorder in mainland China. Although there have been many studies on the parenting of children with autism spectrum disorder in mainland China, there is still a lack of information about the parenting of children with autism spectrum disorder in mainland China. Shock and confusion are common reactions of parents of children with autism spectrum disorder (McCabe, 2008b). Because of the lack of formal medical education, parents have to look for professional and electronic parenting programs to help their children with autism spectrum disorder. For example, a national autism center in China has developed a parenting program for parents of children with autism spectrum disorder. This program includes training parents to help their children with autism spectrum disorder communicate effectively, observing and imitating the behavior of other parents who have successfully helped their children with autism spectrum disorder, and rewarding parents for their efforts. The results show that this program is effective in improving the quality of life of parents of children with autism spectrum disorder (Huang, Jia, & Wheeler, 2012; Sun et al., 2013). Because of the lack of information about the parenting of children with autism spectrum disorder in mainland China, parents of children with autism spectrum disorder often feel isolated and alone. Unfriendly neighbors and teachers often make them feel uncomfortable. To overcome this knowledge gap, this study aims to explore the parenting of children with autism spectrum disorder in mainland China.

## METHOD

### Design

A grounded theory approach was used in this study. The method used in this study is a combination of phenomenological theory and design (Cubbin & Ståhl, 2008). Because the researchers have limited theoretical and empirical knowledge on the parenting of children with autism spectrum disorder in mainland China, they conducted a grounded theory study to explore the parenting of children with autism spectrum disorder in mainland China. The researchers used a combination of qualitative and quantitative methods to explore the parenting of children with autism spectrum disorder in mainland China.

## Participants

Parents (paricipants) were recruited from mainland China through advertisements on the Internet, mainly focusing on the population of children with autism spectrum disorder (ASD). Inclusion criteria included having a child with ASD, being the biological parents of the child, and being able to communicate in Chinese. Exclusion criteria included having a child with other developmental disorders, such as intellectual disability or epilepsy.

Twenty-eight families from mainland China participated in this study. In total, 32 parents participated in 28 interviews. Most of the participants were mothers (only one father participated), from Beijing (from all over China), and one was a man (father of a child with ASD). All participants had one child with ASD.

The mean age of participants was 36.69 ( $SD = 4.54$ ) years. Their educational level varied among high school (4), college degree (16), master's degree (10), and doctoral degree (1). A list is provided in Table 1, the mean age of the children was 6.75 years ( $SD = 4.36$ ). Twenty-one of 28 children were boys and only one was a girl. Twenty-four children had one child in their family and five had siblings. Most children had received one year of applied behavioral analysis and one year of training being common.

## Data Collection

Eight groups of graduate students were asked to conduct the interviews. Each group composed of two or three interviewees. For each interview, one interviewee was principally charged with asking questions while the other took notes and added additional questions if necessary. For the eight local families in Beijing, data were collected by face-to-face interview, and in some cases by telephone. For the 20 families located in other cities, each of them was interviewed individually. Participants were asked to follow the following questions: (1) Who are your children initially important and which family members noticed them? (2) When and how did you notice your child had autism? (3) In what way do you feel he has been diagnosed and how does it affect you? (4) What do you think of him? (5) What are your concerns about him? (6) According to your observations, how have you come to know your child?

All interviews were tape-recorded in high precision. For the face-to-face interviews, a professional recorder, portable, and without a microphone, was used. The recorder was placed on a table and the participant was asked to sit across from the interviewer. For the telephone interviews, one and a half quarts of coffee were given to the participant to drink during the interview.

## Procedures

Before the interview, a consent form and questionnaire on demographic information and family history were sent via email. After the interview, participants were thanked and given 50RMB (about \$8). Video cameras and digital cameras were used to record the participants' reactions to the questions. Participants were encouraged to check their answers and to correct any errors if they had any. This process was repeated until the participants were satisfied with their answers. After the procedure of data analysis, a concierge function of the software was also used to provide feedback.

from which a child had the main goal and the mother of the child, her position was also high. Some mothers from the high-income group had the same view. All the participants agreed or partially agreed and none of them disagreed. For example, one mother said, "Confidence is important, it can help each child to be more confident and to be a good child. Confidence is also a skill that can be learned by all children." .

## Data Analyses

Data analysis was conducted from the beginning of the interview until the end. Generally, the analysis included coding and interpretation. A common approach used in the coding process was open coding, axial coding, and hierarchical coding. The initial code emerged from open coding in which no meaning was derived from line-by-line analysis followed by emergent coding in which (e.g., "a mothering behavior is a life-time problem" was an initial code). When the formal code emerged, axial coding was performed to differentiate between categories (e.g., "a mothering behavior is a life-time problem" was a problem category). Theoretical coding was finally used to identify themes among categories (e.g., connection made between "mothering behavior" and "parenting style of the child"; Chatzma, 2006).

The interview (Chen Li Yi, an experienced clinical psychologist and family therapist, Ting Zhou and Wang Jing Zhou, both graduate students) mainly focused on the mothering behavior and did the coding. Data analysis is a condensed language collection. The codes reflect each other's open coding of finding individual and general codes and combine them into a comprehensive code book based on the first 15 participants. Then meeting emerged held to discuss the common codebook and consolidate. After each discussion, a codebook was developed reflecting common opinions of the participants' data. The first 15 interviews were re-coded and remaining in the interview were coded according to the code book. Discussion emerged held between codes had different opinions. Memo emerged from the code book among them implied by participants' description. Theoretical coding is a condensed collaboration between the three codes, reflecting the connection among them and made.

The credibility of the data is enhanced by triangulation, having collected data from different mothers (in the interview and observation). Confirmation of meaning is through participants' agreement after emerging from the beginning of the interview and the final emerging. A confirmability is achieved by condensing the data going back to the original interview and observing the agreement of the hole coding process a completed. Peer debriefing, in which impartial peer examined general methodology, also involved in improving the quality of the interview (Lincoln & Guba, 1985).

## RESULTS

### Parenting Styles

Participants' parenting styles in four types: training priority, parenting priority, child-rearing alone, and leaving alone (Table 2).

### Training priority

The training-priority parenting style is characterized by the placement of priority on killing the child. Participants' responses showed that they had a strong belief in the importance of training the child and had a positive attitude towards the program. The parents found

TABLE 2  
*Demographic Data of Parents Categorized in Four Parenting Styles*

Parenting Style	Mean Age	Education Level				Occupation	Case Involved
		High School	Bachelor	Master	Doctor		
Taming parenting	38.89	1	4	3	1	Civilian (3), Home wife (2), Engineer (1), Office worker (1), Teacher (1), Companion (1)	#1, 3, 4, 8, 14, 19, 25, 28
Relational hippocendence	38.15	2	4	6	1	Office worker (3), Civilian (2), Teacher (2), Engineer (2), Home wife (2), Companion (1)	#1, 2, 3, 9, 10, 12, 14, 18, 19, 23, 27, 28
Altruistic parenting	33.89	2	5	2	0	Home wife (3), Office worker (2), Civilian (1), Teacher (1), Researcher (1), Engineer (1)	#6, 11, 13, 15, 16, 17, 21, 22, 24
Leaving alone	41.00	0	2	1	0	Manager (1), Computer engineer (1), Office worker (1)	#5, 7, 26

Teaching techniques and tamed man made. During the taming process, he became - all highly demanding and strict. If the child did not concentrate or heed little importance, he often might punish the child: "If he failed to mediate, I would beat him (#3)<sup>1</sup>; "Some time he made me open his mouth to beat him. (#4) This kind of patient emphasized the coach-style more than he came across it. One mother aid, "I have often beaten him strictly 24 hours a day and do not want to leave him. (#19)

The most alien emotion of the patient was an anger, and he clearly described the relational parenting between an anger and high demand in taming. For example, one patient aid, "I became angry and irritable after taming the diagnosis. I had to do something to make me feel better. (#19) In this taming seemed to be a lot of tension between patient and anger. In the patient's description, a kind of cognition exists a connection between anger and inattention taming. First, some patients acknowledged that they were ill-natured or unable to complete the diagnosis, and they cannot find evidence of confirming their child as normal: "When he failed to mediate, I thought he diagnosed as a foreigner. (#8) Second, although some patients aid they had accepted the diagnosis, they were eager to see their child become healthy quickly, for example, "We manage him often to a foreigner at a young age. Otherwise, he prognosis is likely to promising. (#3) Because of the expectation of being identified as the ASD label a common possibility,

<sup>1</sup>Being children are once common in traditional Chinese families. Although this behavior has been described as illegal, it is still illegal. Because of the legal protection of children has not been established, from a perspective of protection of children, it is common to respond to each patient, which contained strong appeal to no beat their child.
